2. Registers

The 8085 contains several registers that temporarily store data and addresses:

- Accumulator (A): The primary register used for arithmetic and data transfer.
- General Purpose Registers (B, C, D, E, H, L): Used for temporary data storage and addressing.
- Program Counter (PC): Holds the address of the next instruction to be executed.
- Stack Pointer (SP): Points to the current top of the stack in memory.

These registers facilitate quick data handling and support instruction execution.

3. Flags Register

The flags register contains individual bits that indicate the status of the ALU operations. The five

main flags are:

- Zero (Z): Set if the result is zero.
- Sign (S): Reflects the sign of the result.
- Parity (P): Set if the number of 1s in the result is even.

The Address Bus specifies memory and I/O locations, while the control signals orchestrate the operation timings. The architecture emphasizes modularity, allowing each component to perform its designated task efficiently.

Core Components of the 8085 Internal Architecture

- Arithmetic and Logic Unit (ALU)

At the heart of the 8085 lies the ALU, which performs all arithmetic operations (addition, subtraction, etc.) and logical operations (AND, OR, XOR, etc.). It interacts closely with the register array to process data, and its operations are controlled via specific control signals.

- Functions:

- Addition and subtraction
- Logical operations
- Data comparison
- Shift and rotate operations (through instructions)

- Highlights:

- Supports 8-bit data operations
- Contains internal flags: Zero (Z), Sign (S), Parity (P), Carry (CY), Auxiliary Carry (AC)

- Register Array

The register array comprises several registers essential for temporary data storage and manipulation:

- General Purpose Registers: B, C, D, E, H, L
- Special Registers:
 - Accumulator (A): Used for arithmetic and logical operations
 - Stack Pointer (SP): Points to the top of the stack
 - Program Counter (PC): Holds the address of the next instruction

These registers are interconnected with the ALU and can be addressed directly or indirectly, depending on the instruction.

- Timing and Control Circuit

This section generates the necessary control signals to coordinate the microprocessor's operations. It receives clock signals and produces timing signals such as:

- ALE (Address Latch Enable): Used to demultiplex address/data lines
- RD (Read): Indicates read operation
- WR (Write): Indicates write operation

- S0, S1, S2: Status signals indicating the current operation stage

The control circuit ensures synchronization among various internal units and external devices, orchestrating seamless data flow.

- Clock Generator

A stable clock signal is vital for synchronizing operations. The 8085's clock generator produces a clock frequency (commonly 3 MHz) derived from an external crystal oscillator, which drives the entire internal circuitry.

- Interrupt Control System

The 8085 supports hardware and software interrupts, allowing responsive interaction with external devices. The interrupt control block manages:

- Interrupt Request (INTR)
- Reset (TRAP)
- Serial Interrupts (RST7.5, RST6.5, RST5.5)

It prioritizes and acknowledges interrupts, enabling the microprocessor to handle multiple sources efficiently.

This unit manages communication with serial devices via the SID (Serial Input Data) and SOD (Serial Output Data) lines. It is especially useful in applications requiring serial communication

protocols.

Address and Data Buses

- Multiplexed Address/Data Bus (AD0-AD7)

The 8085 uses a multiplexed bus system where the same pins carry both address and data signals at different times:

- During the first part of the machine cycle, these pins carry the address.
- During subsequent phases, they carry data.

This multiplexing reduces pin count but necessitates external circuitry (such as latch circuits) to separate address and data signals.

- Address Bus (A8-A15)

These higher-order address lines are un multiplexed and carry the most significant bits of the memory address throughout the cycle. They directly interface with memory and I/O devices.

Data Flow and Instruction Cycle

Understanding the internal architecture's role in data flow provides insight into how the 8085 processes instructions:

- Fetch Cycle: The Program Counter (PC) places the address of the next instruction onto the address bus. The control circuit enables the memory to send the instruction to the Data Bus, which is then loaded into the Instruction Register.
- Decode Cycle: The instruction decoder interprets the instruction and activates the necessary control signals.
- Execute Cycle: Data is transferred between registers, ALU performs calculations, and results are stored back into memory or registers as needed.

The internal architecture ensures these steps are executed in a synchronized manner, governed by the control signals and clock pulses.

External Interface Components

While the internal architecture handles computation and control, the 8085 also interfaces with external devices via:

- Memory Interface: Connects to RAM, ROM, and other memory units.
- I/O Interface: Connects to input/output devices like keyboards, displays, etc.
- Serial Communication: Via SOD and SID lines for serial data transfer.

External interface circuitry, such as latch circuits for address/data demultiplexing, plays a crucial role in facilitating communication with external hardware.
